

18F-Thymidine in Lymphoma: Imaging Proliferation

Andreas K. Buck
Technische Universität München

Molecular imaging of glucose utilization

Potential advantages of imaging proliferation

- FDG-PET (PET/CT): high diagnostic accuracy for (re-)staging and therapeutic monitoring in Hodgkin`s disease and aggressive NHL
- Reduced specificity, tumor grading: 45% in `grey zone` (NHL)
(Schoder et al. JCO 2005)
- Hypothesis: alteration of DNA synthesis reflects cell injury better than glucose utilization

Unspecific FDG-uptake 1 year after remission of aggressive NHL

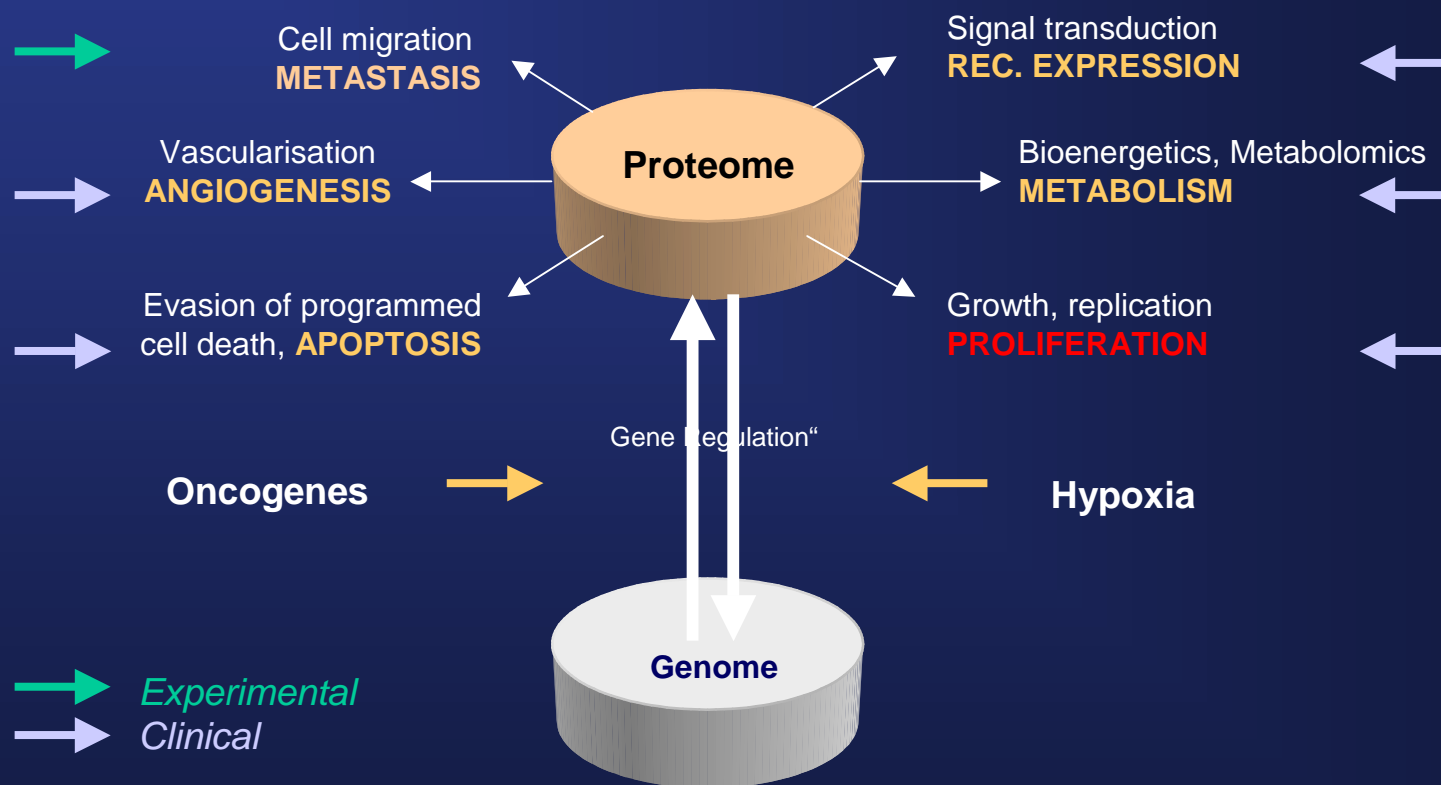

Histology: Lymphadenopathy (courtesy of P. Castellucci, Bologna)

Molecular Probes for PET in Oncology

Wester et al., Clin Cancer Res 2007.

Imaging of Target Systems Cancer

Hanahan and Weinberg
(modified) Cell Press, 2000

Potential advantages of imaging proliferation

- Differentiation viable tumor / inflammatory, benign lesions
- Detection of lymphoma in organs with high physiologic FDG-uptake (brain)
- Tumor grading / transformation to more aggressive histology
- Drug development

Assessment of proliferative activity *in-vitro*

- standard: thymidine analogs
- thymidine not used for RNA synthesis (other than adenine, cytidine and guanine)
- thymidine is taken up by proliferating cells and utilized for synthesis of DNA
 - [³H]Thymidin / TLI
 - *BUdR*
 - *Monoclonal antibodies specific for Ki-67 (MIB-1 mAb, expression during G1-, S- or G2-phase)*
 - *PCNA*

Response assessment with [^{18}F]FLT

- „Inhibition of tumor proliferation may represent an early marker for response to therapy leading to earlier treatment decisions“
- Scans must be reproducible so that serial scans reflect therapy effects
- Reproducibility shown for [^{18}F]FLT microPET and human studies
- moderately low variability -14% (FDG in human studies: 6-10%)

Tseng et al., J Nucl Med 2005.

[¹⁸F]FLT for assessment of therapy response

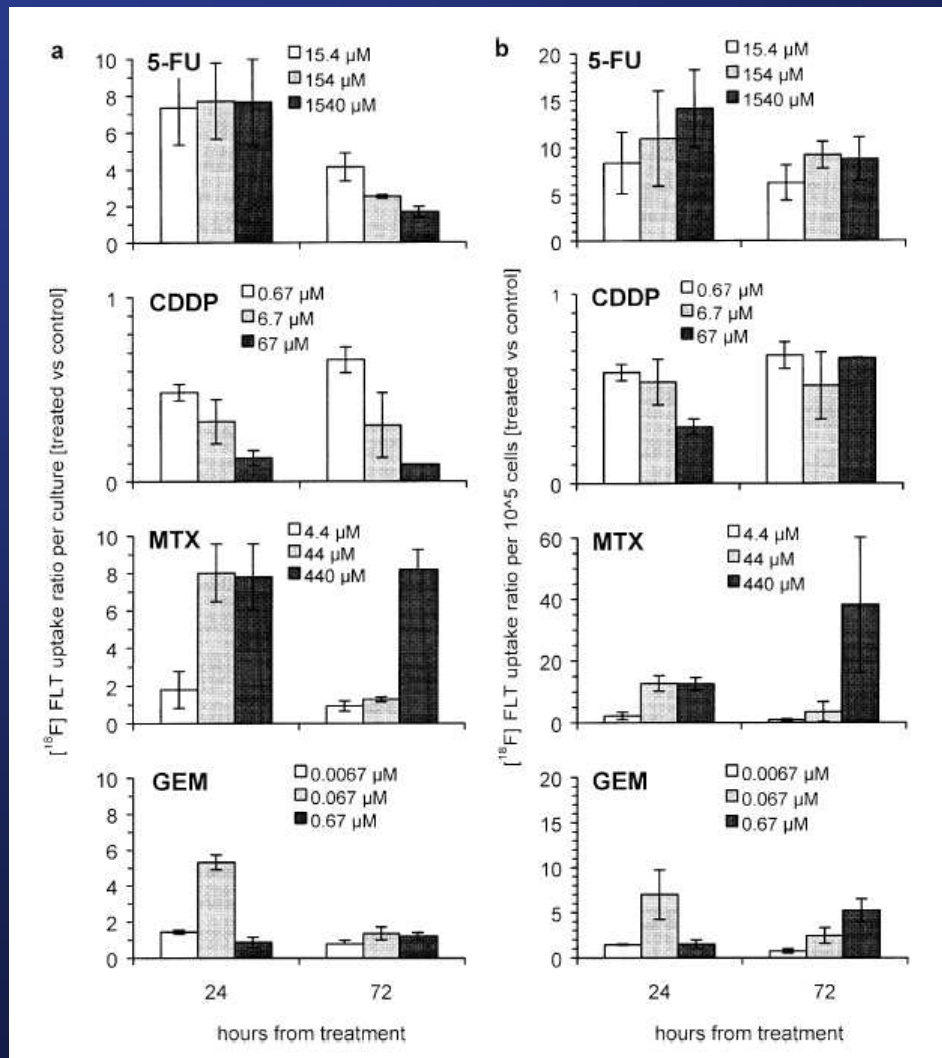

Fig. 2. Cellular uptake of [¹⁸F]FLT per culture (a) or normalised for 10⁵ cells (b) at different doses of 5-FU, MTX, CDDP or GEM. The drug concentrations in the culture media are given in μM. FLT accumulation was measured after 24 or 72 h recovery from treatment. The data are expressed as mean values normalised for the control from repeated experiments, with error bars representing SD

Dittmann et al., EJNMMI 2002.

de novo synthesis of thymidylate and salvage pathway

Chemotherapeutic drugs inhibit thymidylate synthase (TS) or dihydrofolat reductase (DHFR) und can therefore upregulate the salvage pathway (increase of [^{18}F]FLT-uptake)

SHT: serine hydroxymethyl transferase

TK1: thymidine kinase

ENT: equilibrative nucleoside transporter

DHFR: dihydrofolate reductase

dUMP: deoxyuridine monophosphate

CNT: concentrative nucleoside transp.

TS: thymidylate synthase

dTMP: deoxythymidine monophosphate (thymidylate)

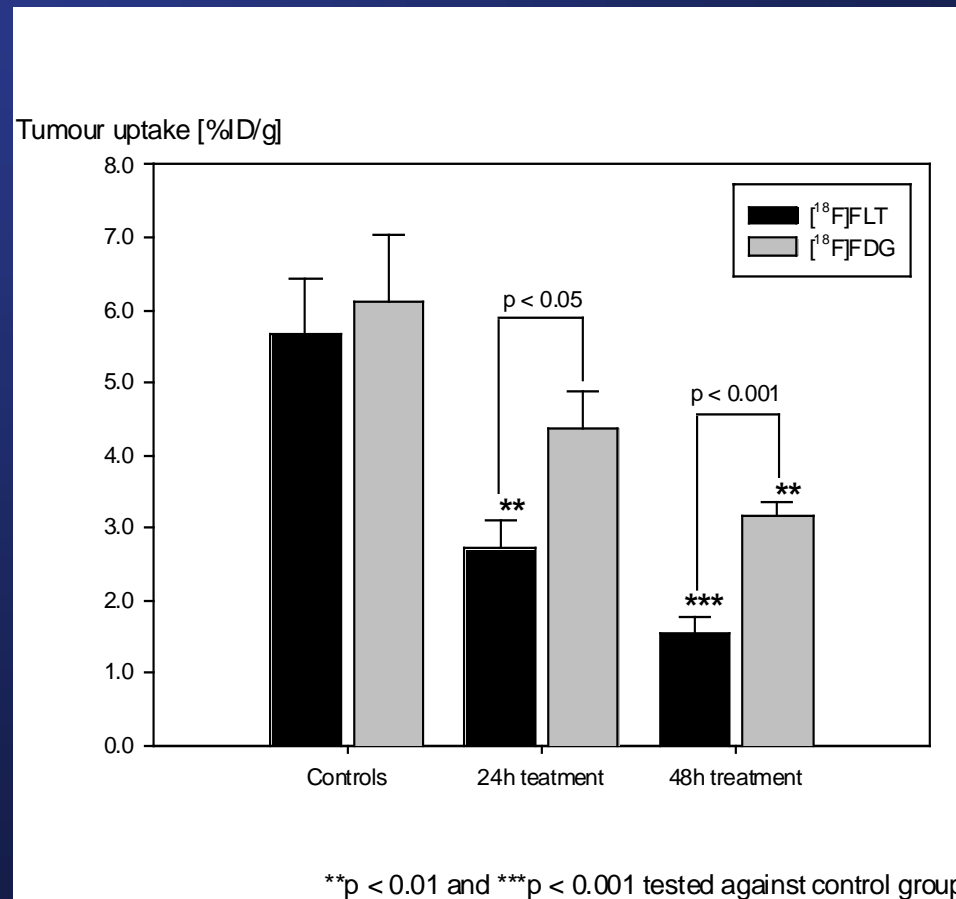

[¹⁸F]FLT- PET in RIF-1 sarcoma mouse model

**Mice harboring transplanted primary lymphomas
with defined genetic lesions
undergo anticancer therapy in vivo**

**Early drug response monitoring
by PET scan**

- FDG-PET (Glucose - energy metabolism)
- FLT-PET (Thymidin - proliferation)

Therapy-induced senescence in *bcl2*-protected $\text{E}\mu\text{-myc}$ lymphomas

Summary

- [^{18}F]FLT reflects (cell cycle-dependent) TK1- activity
- Enables non-invasive assessment of proliferative activity
- Accuracy of [^{18}F]FDG and [^{18}F]FLT for staging almost identical but [^{18}F]FLT superior regarding tumor grading
- anti-proliferative effects of chemotherapy early detectable with [^{18}F]FLT
- DNA-repair and resistance to treatment
- Therapy induced senescence

USE OF 3'-DEOXY-3'-[¹⁸F]FLUOROTHYMININE PET/CT FOR EVALUATING
RESPONSE TO CYTOTOXIC CHEMOTHERAPY IN DOGS WITH
NON-HODGKIN'S LYMPHOMA
